Tuberuclusis is caused by bacteria that infect the lungs and is spread from person to person through the air when someone with TB disease coughs, sneezes, speaks or sings.

TB has two stages: active and latent. TB can only be spread when it is in the active stage, meaning the person infected has symptoms such as a cough that lasts for three or more weeks, fever, weight loss, weakness, and night sweats.

In the latent stage, the TB bacteria live in your body without making you sick. TB is not infectious in this stage. If the bacteria multiply, TB may progress to the active stage.

**Risk Factors:**
- Immigration from a country with a high amount of TB infection
- Coming in contact with someone who has active TB disease
- Having HIV or another disease which impacts the immune system
- Current or history of incarceration for more than six months
- Current or history of travel to a high-risk TB country
- Current or history of homelessness

**Symptoms of active TB disease:**
- Cough for three or more weeks
- Fever
- Weight loss
- Weakness
- Night Sweats

**Active TB case rate per 100,000 population, Wyoming, 2014-2018**

Wyoming has a low incidence of active TB disease. From 2014 to 2018, 10 cases of active TB disease were reported in Wyoming corresponding to an average annual case rate of 0.3 cases per 100,000 population. Teton, Laramie, and Fremont counties each reported two cases of active TB disease. Campbell, Carbon, Natrona, and Park counties each reported one case from 2014-2018.
